

Joint Eurostat/UNECE Work Session on Demographic Projections

29-31 October 20123

A household projection model for Belgium based
on individual household membership rates,
using the LIPRO typology

Marie Vandresse, Federal Planning Bureau (Belgium)

- Discussion

The methodology

General Principles

- A static approach
- The number of individuals by position, gender, age and district is obtained by the following equation:

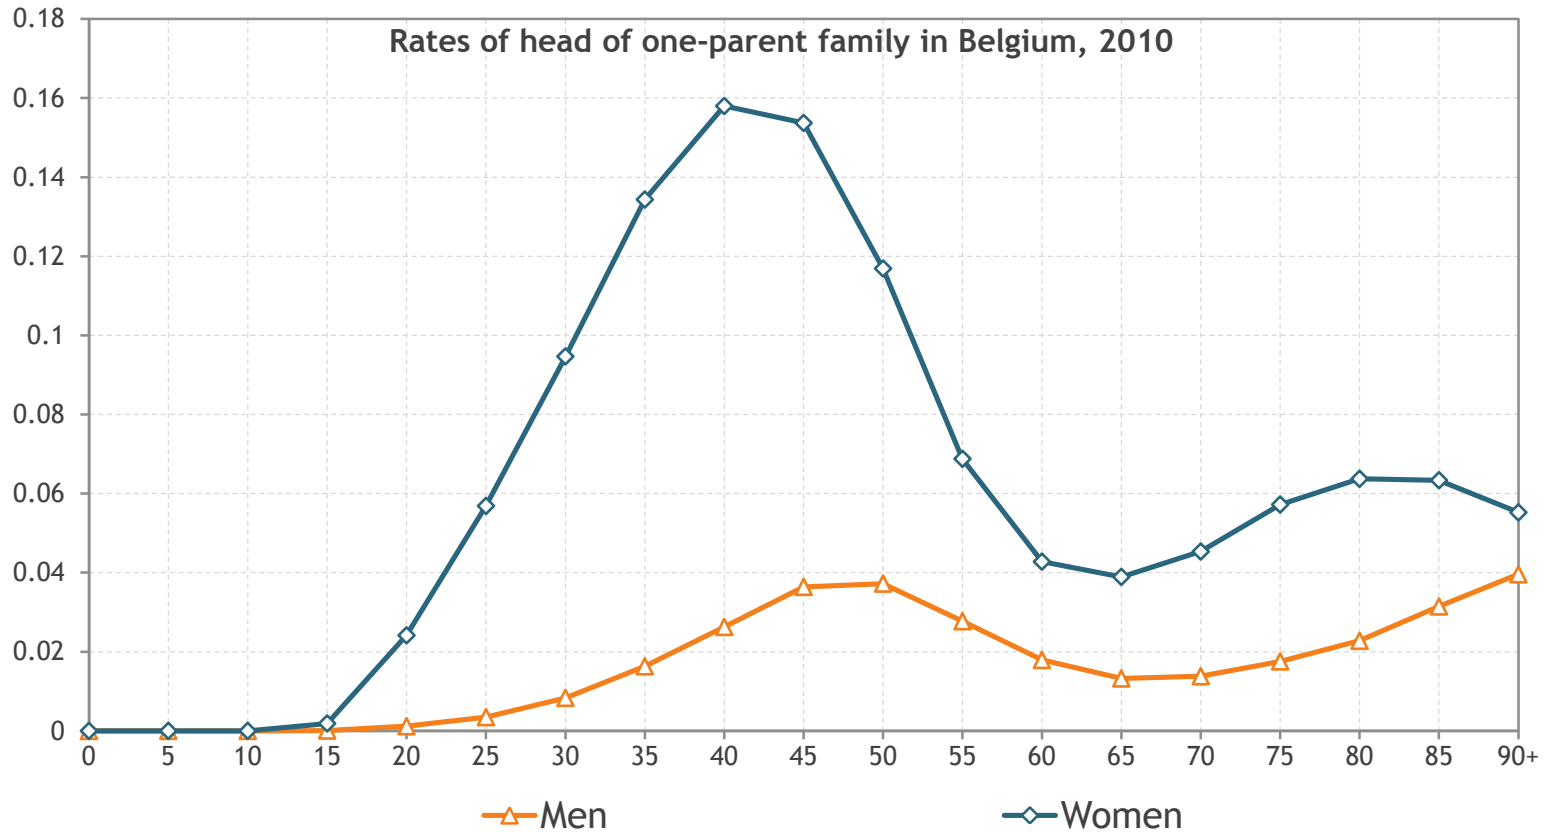

$$I_{HHPOS}_{t,s,y,i}^p = POP_{t,s,y,i} \times T_{HHPOS}_{t,s,y,i}^p$$

Where POP is the population projection and T_HHPOS is the rate of individuals in a position p.

- The projected rates of individuals in a position **by sex, age and district** result from the extrapolation of the observed trends on the last decade (2000-2011), with a saturation effect on the long term.

The methodology

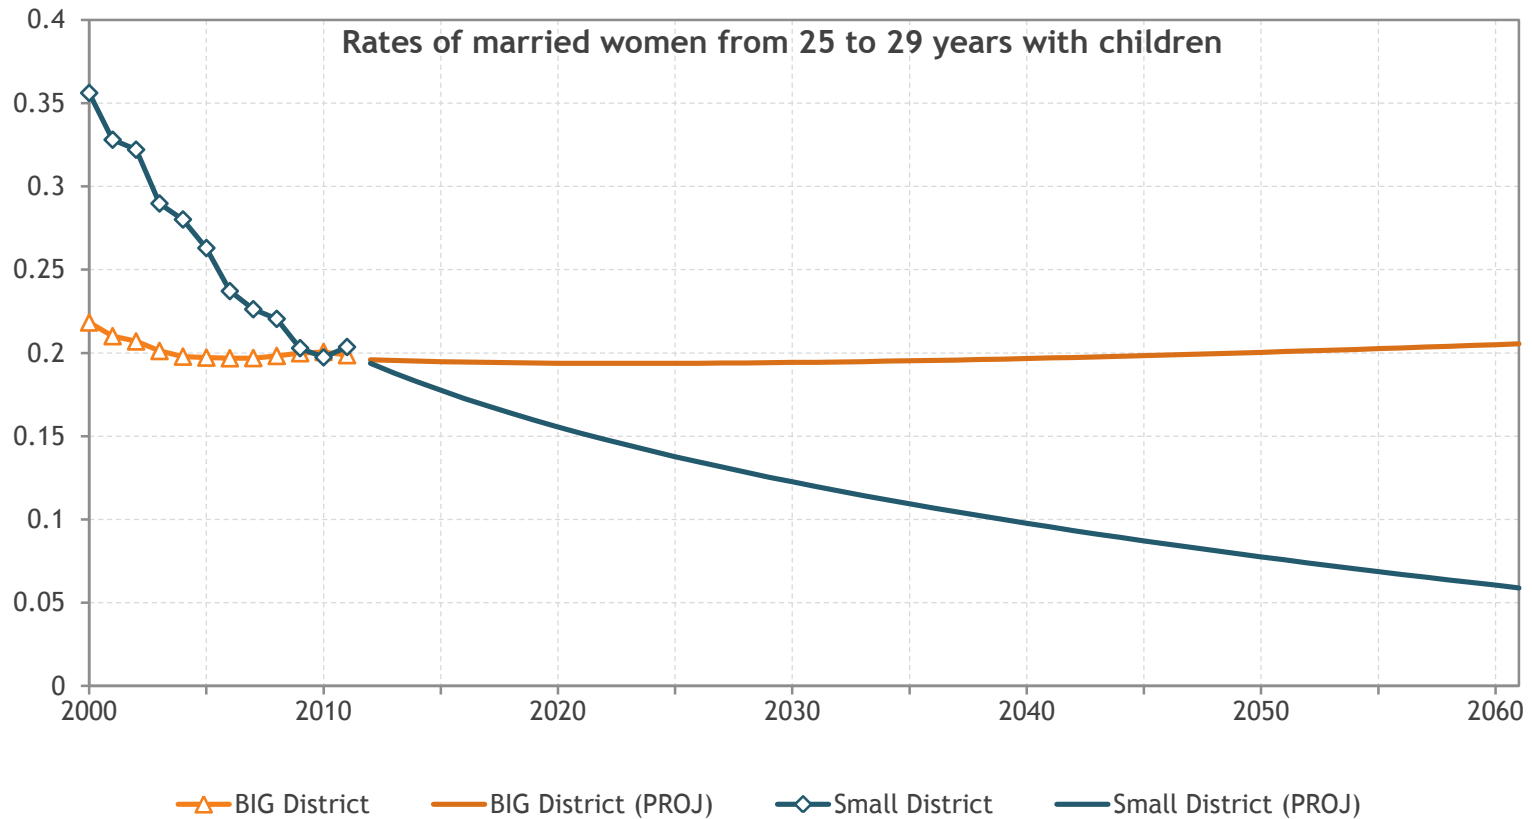

- *The necessity of an estimation by age and gender*

CONCLUSION

- A Static method based on individual living arrangements
- Disadvantage: transition from one position to another one are not considered
- But...
 1. a stock is the result of a flow => the evolution of the stocks follows the evolution of the flows (the transitions)
 2. The evolution of the stock may consequently be interpreted as the summary of the evolution of sociodemographic behaviours.
 3. By hypothesis, the continuation of the recent trends of the rate of individuals in a certain household position assumes a continuation of (recent) past sociodemographic evolutions in living arrangements.

CONCLUSION

- Some basic consistencies' rules are applied (ex: a same number of married women and men).
- The projection of the rates of individuals by position are made by age and gender at the NUTS3 level => local specificities are integrated.
- The projection has been compared with regional projections for Belgium (one of them realised with a multi-state approach), and the results are convergent.

The choice of the hypotheses has certainly a greater impact on the projection's results than the method itself

The results of a projection should always be interpreted while keeping in mind the hypotheses behind the model.
